Childhood Growth and Adult Hypertension in a Population of High Birth Weight

Thorhallur Ingi Halldorsson, Ingibjorg Gunnarsdottir, Bryndis Eva Birgisdottir, Vilmundur Gudnason, Thor Aspelund, Inga Thorsdottir

Abstract—Low birth weight has consistently been associated with increased adult blood pressure. The relative importance of childhood growth is, however, less well established. This study examined sex-specific associations between childhood growth and adult blood pressure in 2120 subjects born from 1921 to 1935 in Reykjavik who were recruited into a longitudinal study in 1967–1991. Size at birth and growth at regular intervals between 8 and 13 years were

Background: Perfluoroalkyl acids are persistent compounds used in various industrial applications. Of these compounds, perfluorooctanoate (PFOA) is currently detected in humans worldwide. A recent study on low-dose developmental exposure to PFOA in mice reported increased weight and elevated biomarkers of adiposity in postpubertal female offspring.

Objective: We examined whether the findings of increased weight in postpubertal female mice could be replicated in humans.

Methods: A prospective cohort of 665 Danish pregnant women was recruited in 1988–1989 with

PFAAs are found in highest concentrations in the liver (Hundley et al. 2006; Maestri et al. 2006) and low-dose human exposures to PFOA and PFOS have been associated with modest increases in liver enzymes (Lin et al. 2010) and blood lipids (Nelson et al. 2010) in cross-sectional settings. The relevance of these findings is uncertain, however, because prospec-

An alternative for examining cardiometabolic risk factors

Not published

Cardiometabolic risk fators

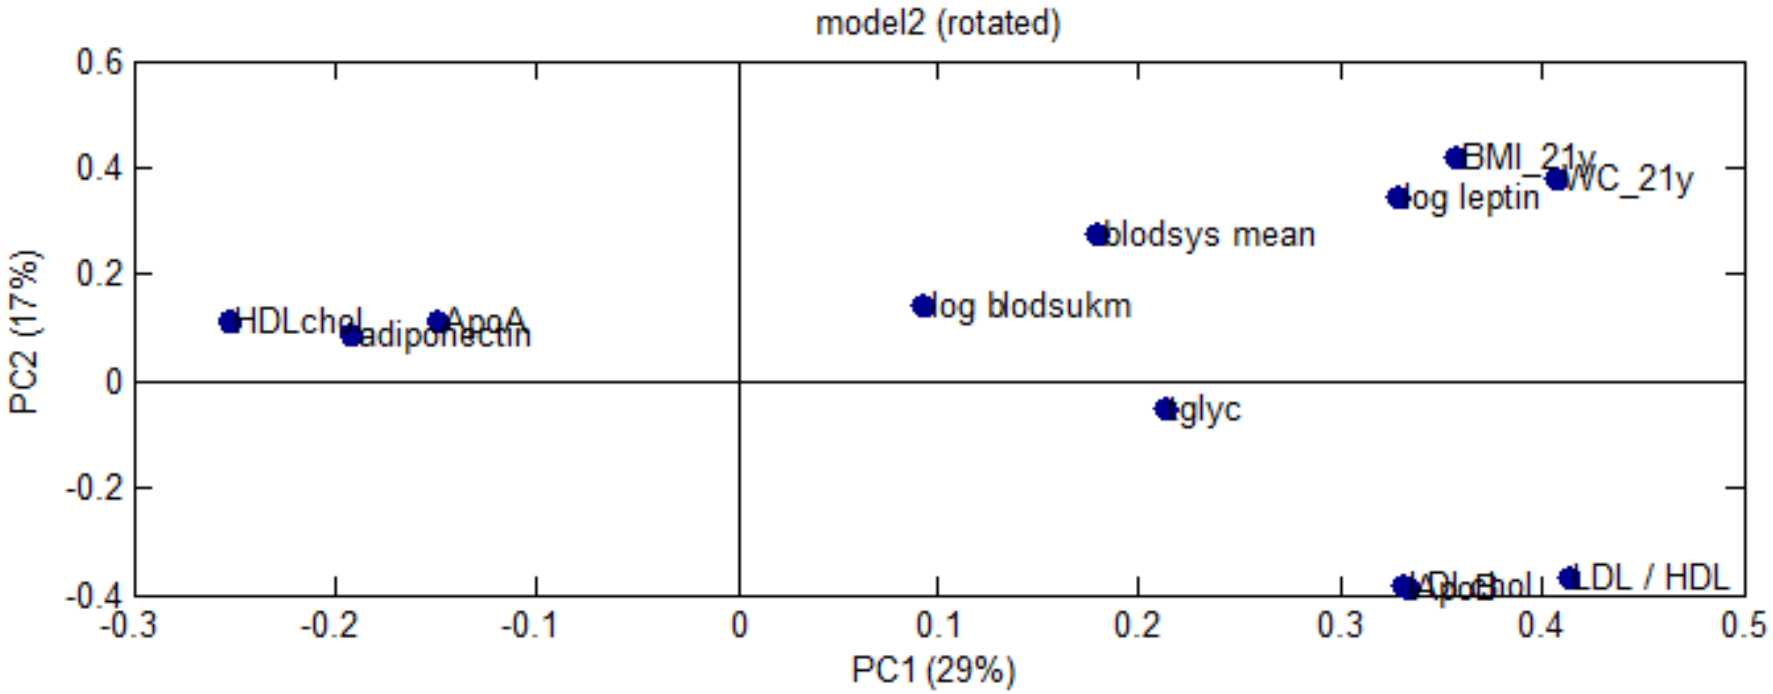
- Number of samples is 422 (170 males and 252 females)

- Included in this analysis (11 primary, 1 derived):
  - Systolic BP mean across three reg.
  - Fasting sugar
  - LDLchol
  - HDLchol
  - tglyc
  - BMI
  - Waist corcumference
  - LDL / HDL (a constructed ratio)
  - ApoA
  - ApoB
  - Adiponectin
  - leptin

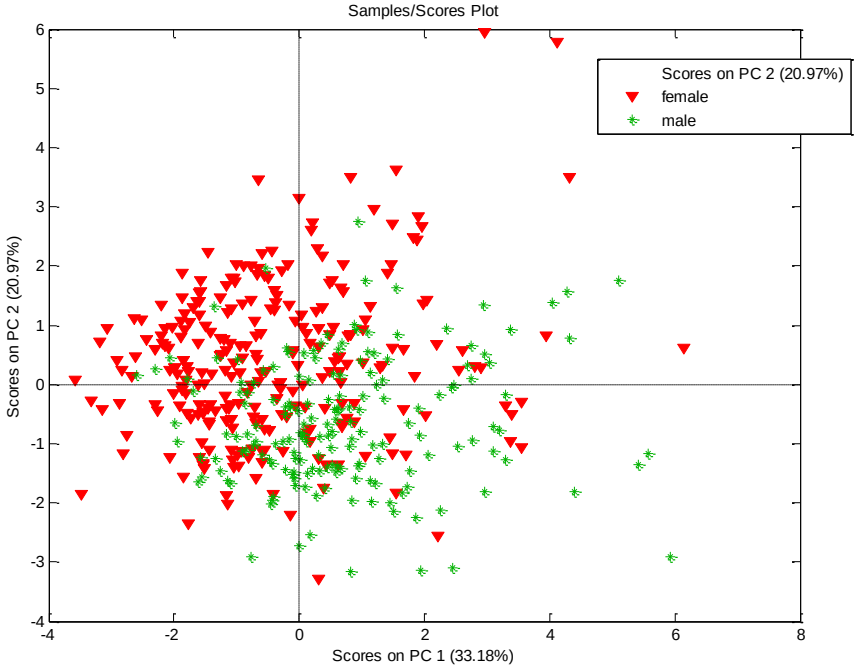
The two main components

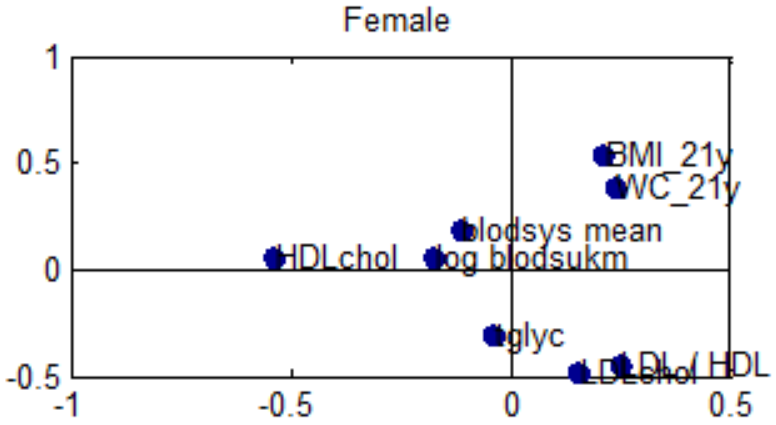
- Explainins 46% of the total variation

- PC1 (29%): Adiposity and associated cardiometabolic risk factors
- PC2(17%): normal weight but adverse lipid profile



- The patterns are consistent between the two sexes
- There is a offset between but the structure is similar





Results for the PCA

Associations of *in Utero* Exposure to Perfluorinated Alkyl Acids with Human Semen Quality and Reproductive Hormones in Adult Men

Anne Vested,[1] Cecilia Høst Ramlau-Hansen,[1,2] Sjurdur Frodi Olsen,[3] Jens Peter Bonde,[4] Susanne Lund Kristensen,[1] Thorhallur Ingi Halldorsson,[3,5] Georg Becher,[6] Line Småstuen Haug,[6] Emil Hagen Ernst,[7] and Gunnar Toft[1]

[1]Danish Ramazzini Centre, Department of Occupational Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Public Health, Section of Epidemiology, University of Aarhus, Aarhus, Denmark; [3]Centre for Fetal Programming, Statens Serum Institut, Copenhagen, Denmark; [4]Department of Occupational and Environmental Medicine, Bispebjerg Hospital of Copenhagen University, Copenhagen, Denmark; [5]Faculty of Food Science and Nutrition, University of Iceland, Reykjavik, Iceland; [6]Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway; [7]Reproductive Laboratory, Institute of Anatomy, University of Aarhus, Aarhus, Denmark

Results: Multivariable linear regression analysis suggested that *in utero* exposure to PFOA was associated with lower adjusted sperm concentration (p_{trend} = 0.01) and total sperm count (p_{trend} = 0.001) and with higher adjusted levels of luteinizing hormone (p_{trend} = 0.03) and follicle-stimulating hormone (p_{trend} = 0.01). PFOS did not appear to be associated with any of the outcomes assessed, before or after adjustment.

Conclusions: The results suggest that *in utero* exposure to PFOA may affect adult human male semen quality and reproductive hormone levels.

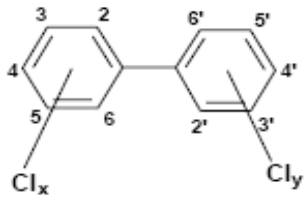
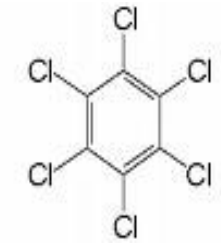
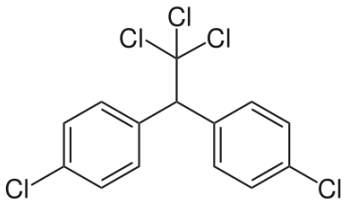
So what about other contaminants ?



PCBs

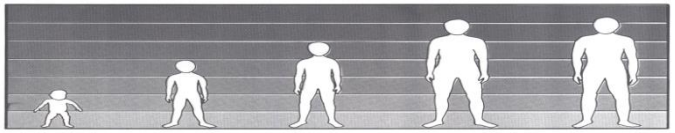


HCB



DDT

Limitations



PFOA

Offspring follow up at ~20 years

PFOA

- Despite consistent findings in one animal and one human observational study, other studies have not replicated these findings.
- Unlike those studies our opulation consisted of predominantly (92%) normal weight women.
- Exposure to PFOA could reflect unhealthy dietary habits (fast food)
- Difficult to repleicate findings of lon term-followup studies as lifestyl habits change.

In contrast to chemical exposures where we aim to minimize exposure and protect consumers …..

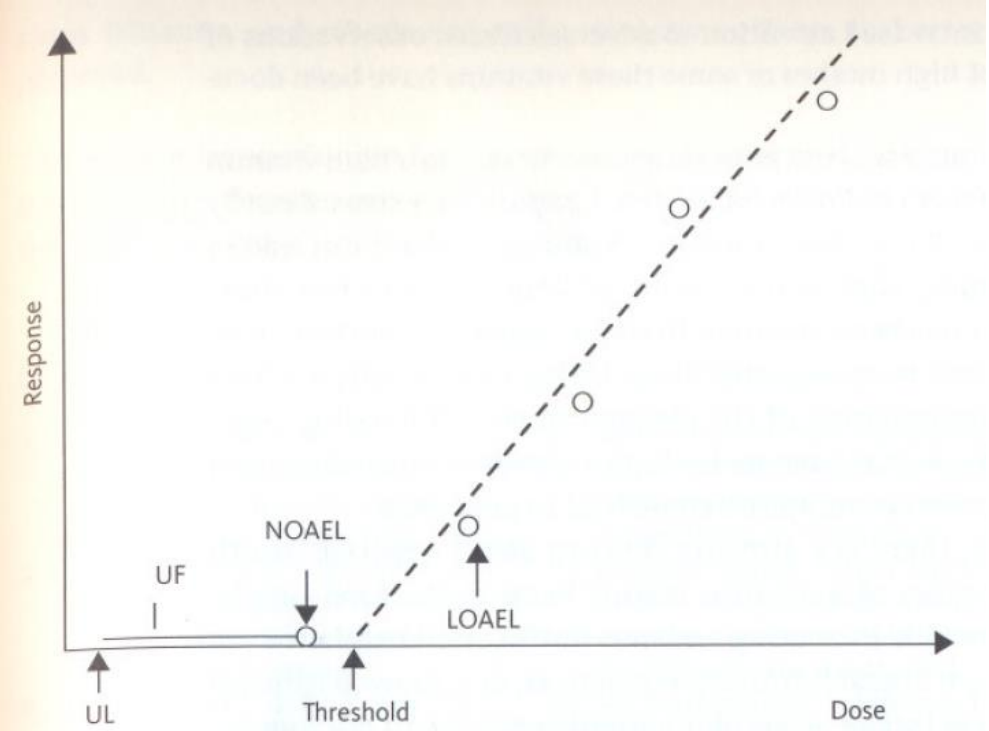


Figure 3.4 Derivation of upper intake level (UL)

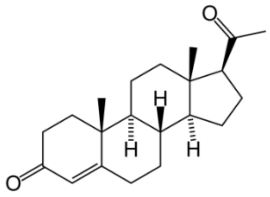

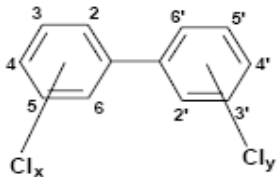

PFOA (Perfluorooctanoic acid)

We are often more relaxed about unhealthy lifestyles (….although the “effects“ are no better or worse)

What is the source of this variation

ORIGINAL ARTICLE

Gestational weight gain in normal weight women and offspring cardio-metabolic risk factors at 20 years of age

L Hrolfsdottir[1], D Rytter[2], SF Olsen[3,4], BH Bech[2], E Maslova[3], TB Henriksen[5] and TI Halldorsson[1,3]

OBJECTIVE: Limited knowledge exists on the long-term implications of maternal gestational weight gain (GWG) on offspring health. Our objective was to examine whether high GWG in normal weight women is associated with adult offspring cardio-metabolic risk factors.

Table 3. Associations of maternal gestational weight gain with offspring BMI and waist circumference at follow-up ($n = 308$)

	Offspring BMI ($kg\ m^{-2}$)		*Offspring overweight*	
	β[a]	*95% CI*	*OR*[b]	*95% CI*

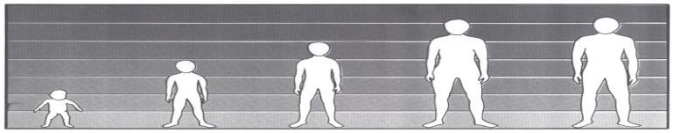
[a]Showing increase in the outcome variable per 1-kg increase in gestational weight

Limitations



Gestational weight gain

Offspring follow up at ~20 years

- Our findings are consistent with results from other similar studies.
- The relevance of GWG as a risk factor for adverse metabolic health is still far from clear.
- Confounding due to clustering of familial lifestyle factors is difficult to account for as the offspring environment is continuously changing

What is the source of this variation

…**and how dose it affect later growth and health**

Environmental chemicals

Maternal weight gain

Maternal diet

In the case of diet, adverse consequences should in theory only occur at the extremes

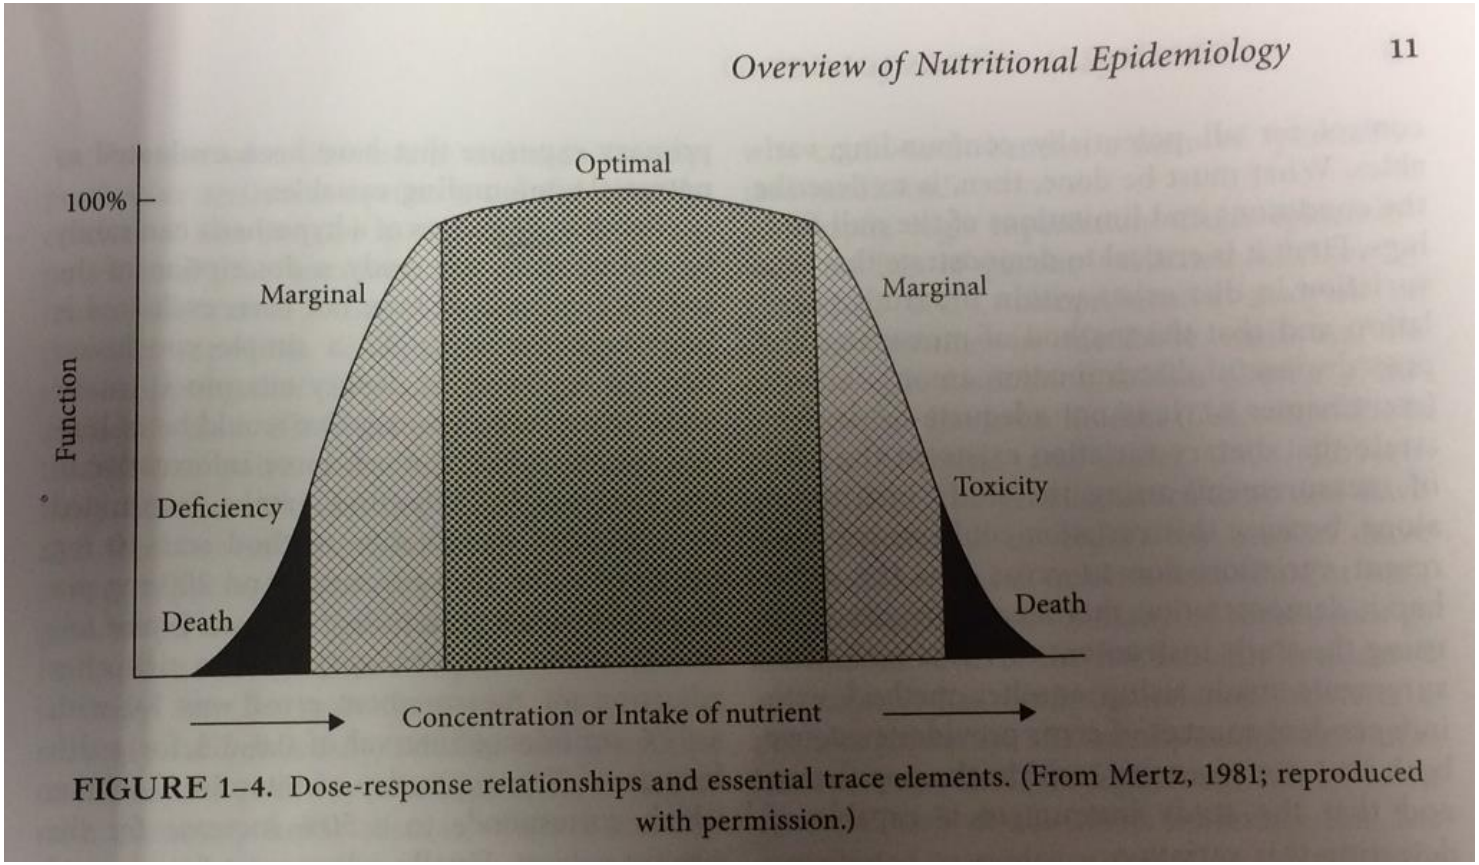


FIGURE 1–4. Dose-response relationships and essential trace elements. (From Mertz, 1981; reproduced with permission.)

Macronutrient intake

- **Protein** should provide 10-20% of total energy intake (E%).

- **Carbohydrates** 45-60 of E%
  - refined sugars < 10 E%
  - fibers should be 25-35 g/day

- **Fats** 25-40% of total energy (E%)
  - Saturated fatty acids < 10 E%
  - (Cis-)monounsaturated acids 10-20 E%
  - Polyunsaturated acids 5-10 E%,
    - icluding approx 1% from n-3 fatty acids

In historical context

- **Much emphasis of reducing intake of saturated fat (sfa) in tthe 1980s and 1990s due to its link with CVD**

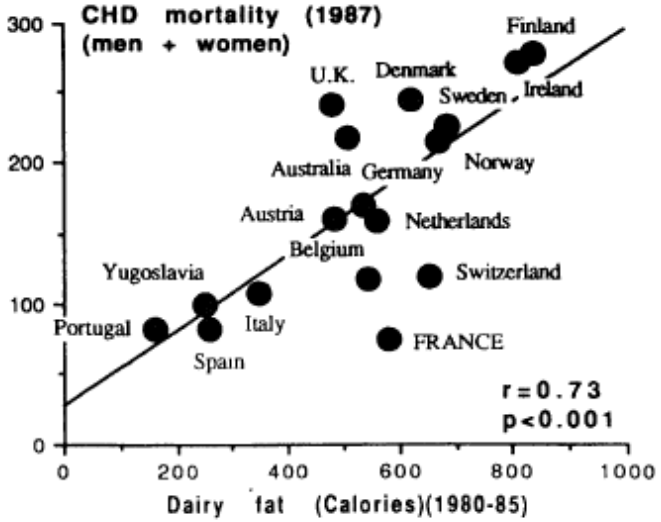

Fig 1—Relation between age-standardised death rate from CHD (mean for men and women)[1] and consumption of dairy fat in countries reporting wine consumption.

Regression equation: y = 26·3 + 0·27 dairy fat

E = constant

Pediatrics

A Randomized Controlled Trial of Prenatal Nutritional Supplementation in New York City

David Rush, MD, Zena Stein, MA, MB, BCh, and Mervyn Susser, MB, BCh, DPH, FRCP(E)

The Harlem Trail

- *Aim of study was to increase birth weight and influence the postnatal development of the offspring of mothers at high risk of having low birth weight infants*

- 3-arm beverage supplemental trail:
  - **Controls:** received no protein supplementation
  - **Complimental group**: received balanced protein supplementation (6g/day casein)
  - **Supplemental group**: received high protein supplementation (40g day casein)

- <u>All three groups all received micronutrient supplementation</u>

The Harlem Trail

ABSTRACT

Background: Animal studies have shown that protein intake in pregnancy may influence offspring fat metabolism and adiposity. The macronutrient ratio in human pregnancy appears to be important for offspring glucose tolerance; however, less is known about the influence on offspring adiposity.

Objective: We examined the relation between maternal dietary protein intake during pregnancy and offspring anthropometric measures and biomarkers of adiposity and glucose metabolism.

Relation between protein (substituted for carbohydrates) intake in pregnancy and risk of offspring being overweight or having waist circumference above action level II at 19–21 y of age for women (n = 361) and men (n = 325)[1]

	Overweight (BMI ≥25 kg/m^2)		High waist circumference

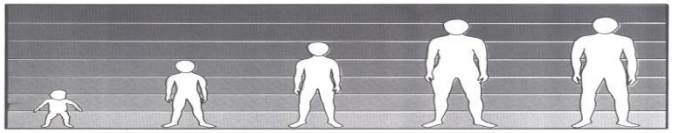
[1] All values are RRs; 95% CIs in parentheses. The total protein model was adjusted for fat intake and total energy; the animal protein model was adjusted for vegetable protein, other protein, fat, and total energy; and the vegetable protein model was adjusted for animal protein, other protein, fat, and total energy.

Limitations



In utero exposure

Offspring follow up at ~20 years

- Allot of room for confounding - **Clustering of familial lifestyle factors**
- Even with detailed information on later maternal offspring dietary habits proper adjustment may be difficult
- However, In the correlation between maternal versus offspring macronutrient intake among adolecants is often around ~0.1 to 0.3

Conclusions

- In small comprehensive birth cohort with long term follow-up a large number of associations betwene prenatal variables and ofssrping CVD-risk profile can be demonstrated.

- **Limitations**
  - As always there are questionmarks on causality of findings
  - Questions on biological relevance for some of these findings
  - Postnatal confunding cannot be exclued (unlikley to aplly for all findings)
  - Even with complete infomrmation, controling for postnatal factors is almost impossible

Conclusions

- In small comprehensive birth cohort with long term follow-up a large number of associations betwene prenatal variables and ofssrping CVD-risk profile can be demonstrated.

- **Strengths:**
  - Environmental exposure, maternal diet and GWG are all modifayable lifestlye habtis. Better characterisation of these factors in terms of later offspring health has clear public health relevance.
  - Our findings strongly suggest that variation in dietary and environmental exposures “within normal range“ may have biological (but not always clinically relevant) “effect“
  - Our results also higlight the need of not overinterpreting individual findings in terms of what is the “most important risk factor“!!

A recent reviewer coment
- to a rejected DaFo88 paper -

- A number of studies start with a cohort of births and follow the offspring over time. Perhaps the most famous of these studies is a sequence of UK birth cohort studies started in 1946 and reported on extensively in the book, The Life Project by Helen Pearson. A very large number of variables are measured on parent(s), birth characteristics, and offspring. The offspring are studied over time, usually to early adulthood.

- Given the number of variables available and the number of covariates, drawing valid conclusions is challenging. Suppose there are 10 characteristics of the parent(s), 10 birth characteristics, 10 characteristics of the newborn child and 10 characteristics measured every five years until and including 20 years old. We would have 10^7 possible relationships. Some relationships would not be of interest, but many would. The standard of 5% for statistical significance would lead to an enormous number of “statistically significant” false positive results.

- Multiple testing needs to be carefully considered and dealt with.

BMJ 2014;348:g1285 doi: 10.1136/bmj.g1285 (Published 10 February 2014)

RESEARCH

Antenatal lifestyle advice for women who are overweight or obese: LIMIT randomised trial

Jodie M Dodd *professor of obstetrics and gynaecology; maternal fetal medicine specialist*[1 2], Deborah

Abstract

Objective To determine the effect of antenatal dietary and lifestyle interventions on health outcomes in overweight and obese pregnant women.

Design Multicentre randomised trial. We utilised a central telephone randomisation server, with computer generated schedule, balanced variable blocks, and stratification for parity, body mass index (BMI) category, and hospital.

Setting Three public maternity hospitals across South Australia.

Participants 2212 women with a singleton pregnancy, between 10+0 and 20+0 weeks' gestation, and BMI ≥25.

Interventions 1108 women were randomised to a comprehensive dietary and lifestyle intervention delivered by research staff; 1104 were randomised to standard care and received pregnancy care according to local guidelines, which did not include such information.

Main outcome measures Incidence of infants born large for gestational age (birth weight ≥90th centile for gestation and sex). Prespecified secondary outcomes included birth weight >4000 g, hypertension, pre-eclampsia, and gestational diabetes. Analyses used intention to treat principles.

Results 2152 women and 2142 liveborn infants were included in the analyses. The risk of the infant being large for gestational age was not significantly different in the two groups (lifestyle advice 203/1075 (19%) *v* standard care 224/1067 (21%); adjusted relative risk 0.90, 95% confidence interval 0.77 to 1.07; P=0.24). Infants born to women after lifestyle advice were significantly less likely to have birth weight above 4000 g (lifestyle advice 164/1075 (15%) *v* standard care 201/1067 (19%); 0.82, 0.68 to 0.99; number needed to treat (NNT) 28, 15 to 263; P=0.04). There were no differences in maternal pregnancy and birth outcomes between the two treatment groups.

Conclusions For women who were overweight or obese, the antenatal lifestyle advice used in this study did not reduce the risk delivering a baby weighing above the 90th centile for gestational age and sex or improve maternal pregnancy and birth outcomes.

Trial registration Australian and New Zealand Clinical Trials Registry (ACTRN12607000161426).

RESEARCH

Low glycaemic index diet in pregnancy to prevent macrosomia (ROLO study): randomised control trial

Jennifer M Walsh *clinical research fellow, specialist registrar in obstetrics and gynaecology*, Ciara A McGowan *research dietician*, Rhona Mahony *consultant obstetrician and gynaecologist*, Michael

Abstract

Objective To determine if a low glycaemic index diet in pregnancy could reduce the incidence of macrosomia in an at risk group.

Design Randomised controlled trial.

Setting Maternity hospital in Dublin, Ireland.

Participants 800 women without diabetes, all in their second pregnancy between January 2007 to January 2011, having previously delivered an infant weighing greater than 4 kg.

Intervention Women were randomised to receive no dietary intervention or start on a low glycaemic index diet from early pregnancy.

Main outcomes The primary outcome measure was difference in birth weight. The secondary outcome measure was difference in gestational weight gain.

Results No significant difference was seen between the two groups in absolute birth weight, birthweight centile, or ponderal index. Significantly less gestational weight gain occurred in women in the intervention arm (12.2 *v* 13.7 kg; mean difference −1.3, 95% confidence interval −2.4 to −0.2; P=0.01). The rate of glucose intolerance was also lower in the intervention arm: 21% (67/320) compared with 28% (100/352) of controls had a fasting glucose of 5.1 mmol/L or greater or a 1 hour glucose challenge test result of greater than 7.8 mmol/L (P=0.02).

Conclusion A low glycaemic index diet in pregnancy did not reduce the incidence of large for gestational age infants in a group at risk of fetal macrosomia. It did, however, have a significant positive effect on gestational weight gain and maternal glucose intolerance.

Trial registration Current Controlled Trials ISRCTN54392969.

OBSTETRICS

The Treatment of Obese Pregnant Women (TOP) study: a randomized controlled trial of the effect of physical activity intervention assessed by pedometer with or without dietary intervention in obese pregnant women

Kristina M. Renault, MD; Kirsten Nørgaard, DMSc; Lisbeth Nilas, DMSc; Emma M. Carlsen, MD; Dina Cortes, DMSc; Ole Pryds, DMSc; Niels J. Secher, MD

Women with pre-preg BMI>30kg/m^2

Main outcome: Gestational weight gai

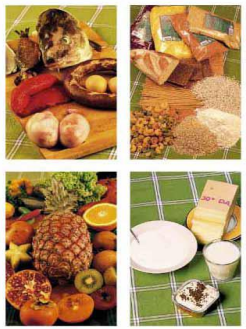
Randomised
N=425

Allocation

Intervention group
PA+D)
n=142
FFQ n=135

Intervention group PA)
n=142
FFQ n=132

Control group C)
n=141
FFQ n=129



Results: Primary outcome of the TOP-study

N=389	PA+D) Diet + Pedometer n=130	PA) Pedometer n=125	C) Control n=134	Significance
GWG: Median	**8.6 kg**	**9.4 kg**	**10.9kg**	*P*=0.024

❖Pedometer intervention reduced GWG by a mean of 1.4 kg compared to women not using a pedometer

❖Additive effect of dietary follow-up was not significant

Why are the effect estimates so unimpressive

RESEARCH ARTICLE

Intake of Sweets, Snacks and Soft Drinks Predicts Weight Gain in Obese Pregnant Women: Detailed Analysis of the Results of a Randomised Controlled Trial

Kristina M. Renault[1,2]*, Emma M. Carlsen[3], Kirsten Nørgaard[4], Lisbeth Nilas[1], Ole Pryds[3], Niels J. Secher[5], Sjurdur F. Olsen[6,7], Thorhallur I. Halldorsson[6,8]

A validated food frequency questionnaire (FFQ)

360-items

Covered the intake of food and drinks during previous 4 weeks

Baseline: Week 11-14

Endpoint: Week 36-37

Changes in diet

Table 2. Relative changes in dietary intake between baseline and endpoint among subjects reporting their diet at both time points (N = 342). The relative risk of having either low or excessive weight gain as defined by the institute of medicine[1] is also shown for each group.

	Control (n = 118)	Physical Activity (n = 110)	Physical Activity + Diet (n = 114)
Changes in dietary intake		Δ^2 (95% CI)	Δ^2 (95% CI)
Energy (MJ/day)	Reference	-0.0 (-0.7, 0.7)	0.1 (-0.5, 0.8)
Protein (%E)	Reference	0.3 (-0.4, 1.0)	**1.0 (0.3, 1.7)**
Animal protein	Reference	0.0 (-0.8, 0.9)	**1.1 (0.2, 1.9)**

TABLE 2
Associations between digestible carbohydrates in early and late pregnancy in relation to the relative fat mass of offspring as measured by dual-energy X-ray absorptiometry 24 h after delivery

		Change[1] (95% CI), %	
	Median intake, g/d	Unadjusted	Adjusted[2]
Weeks 11–14			
Quartile 1	180	Referent	Referent
Quartile 2	205	0.4 (−1.2, 2.1)	1.0 (−0.5, 2.5)
Quartile 3	220	0.9 (−0.8, 2.5)	0.9 (−0.6, 2.5)
Quartile 4	244	1.2 (−0.5, 2.8)	1.2 (−0.3, 2.7)
P-trend		0.14	0.14
Weeks 36–37			
Quartile 1	188	Referent	Referent
Quartile 2	205	1.0 (−0.7, 2.6)	0.6 (−0.9, 2.1)
Quartile 3	217	1.2 (−0.5, 2.8)	0.9 (−0.7, 2.4)
Quartile 4	238	2.4 (0.7, 4.0)	2.1 (0.6, 3.7)
P-trend		0.005	0.006

[1]Mean increase in the relative percentage fat of the offspring compared with the value in quartile 1.

[2]Adjusted for maternal age, physical activity intervention, prepregnancy BMI, parity, gestational weight gain, gestational age, smoking during pregnancy, 2-h oral-glucose-tolerance test value (at approximately week 29), energy intake, and offspring sex and age at the time of the dual-energy X-ray absorptiometry measurement.

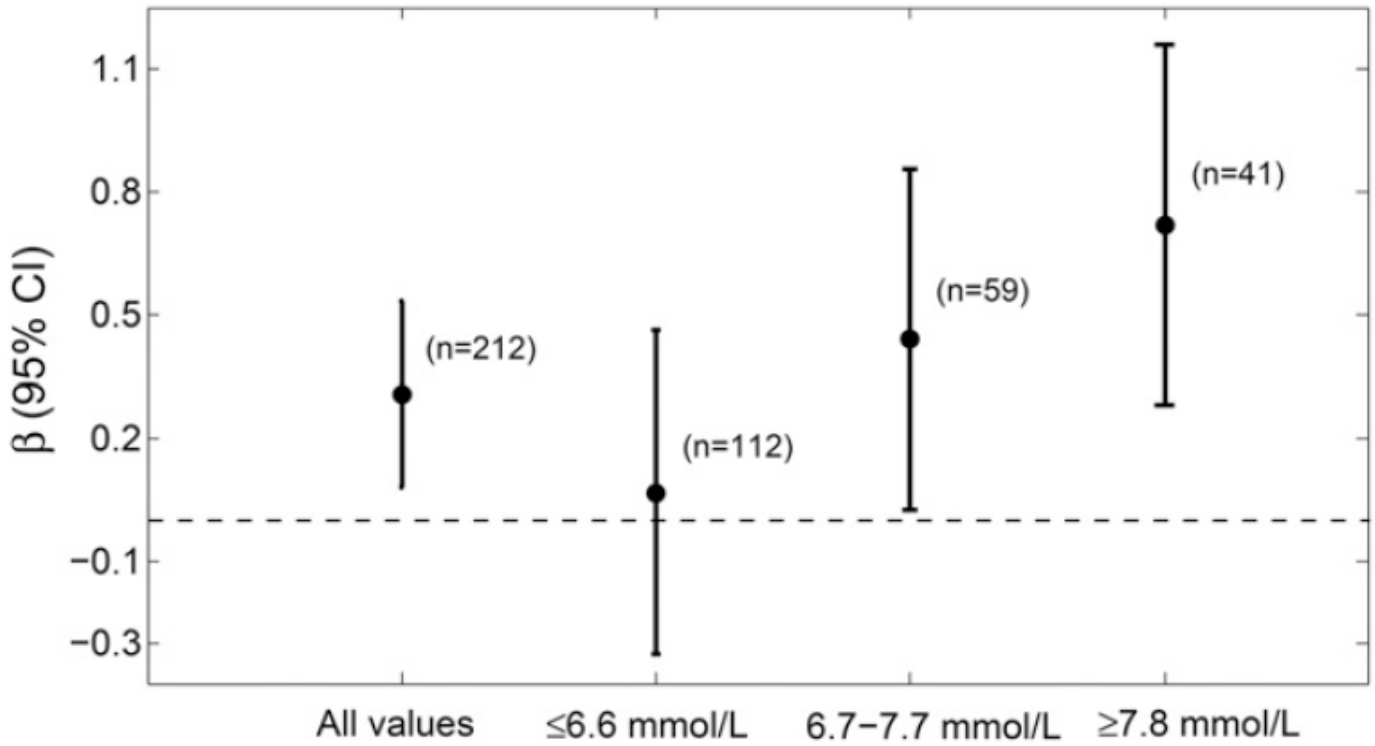

FIGURE 2 Associations between intake of digestible carbohydrates at gestational weeks 36–37 and relative fat mass of the offspring measured by dual-energy X-ray absorptiometry after birth. The regression coefficients reflect the change in relative fat mass (% on the *y* axis) per 10-g higher intake of digestible carbohydrates for all values and coefficients based on stratification by maternal 2-h oral-glucose-tolerance test values in the third trimester.

Fructose: the poison index

A ruling on fructose boosts the powerful sugar industry, either by incompetence or collusion, but is based on pseudoscience

Robert Lustig
The Guardian, Monday 21 October 2013 21.00 BST
Jump to comments (721)

Fizzy drinks can have a 'serum fructose concentration of six micromolar, enough to do major arterial and pancreatic damage'. Photograph: Nathalie Louvel/Getty Images

The battle over the compound fructose now reaches new levels of obfuscation. The food industry is a strong – and loud, and rich – proponent, hard to ignore. The European Food and Safety Agency has just weighed in, in favour of the substitution of sucrose (table sugar: a disaccharide composed of the monosaccharides glucose and fructose)

The Panel considers that in order to bear the claim, glucose or sucrose should be replaced by fructose in sugar sweetened foods or beverages. The target population is individuals who wish to reduce their post-prandial glycaemic responses. The Panel notes that high intakes of fructose may lead to metabolic complications such as dyslipidaemia, insulin resistance and increased visceral adiposity.
